TUPLES OF HYPERELLIPTIC CURVES $y^2 = x^n + a$

TOMASZ JĘDRZEJAK, JAAP TOP, AND MACIEJ ULAS

ABSTRACT. In this paper it is shown that, given $n \in \mathbb{Z}_{\geq 3}$ and $a, b, c \in \mathbb{Q}^\times$, there exists a polynomial $d(t) \in \mathbb{Q}[t]$ such that the curves over $\mathbb{Q}(t)$ given by $y^2 = x^n + ad(t)$ resp. $y^2 = x^n + bd(t)$ and $y^2 = x^n + cd(t)$ all have a Jacobian with positive Mordell-Weil rank over $\mathbb{Q}(t)$. Extensions of this result to sets of four curves are discussed, as well as the problem of demanding in addition that $d(t)$ is a square.

1. INTRODUCTION

Kuwata and Wang in [Ku] considered the surface $\mathcal{E}$ given by

$$\mathcal{E} : (x_1^3 + ax_1 + b)y^2 = x_2^3 + cx_2 + d$$

where $a, b, c, d \in \mathbb{Q}$ satisfy $(a, c) \neq (0, 0) \neq (b, d)$. Considering the Euclidean topology on the set $\mathcal{E}(\mathbb{R})$ of all real points on $\mathcal{E}$, they show that the set of rational points $\mathcal{E}(\mathbb{Q})$ is dense in $\mathcal{E}(\mathbb{R})$. Their argument uses a special rational curve on $\mathcal{E}$, which was independently also constructed by Mestre in [Me]. Using this rational curve, Kuwata and Wang deduce the corollary that if E_1, E_2 are elliptic curves over $\mathbb{Q}$ with j -invariants $(j(E_1), j(E_2)) \notin \{(0, 0), (1728, 1728)\}$, then a polynomial $d(t) \in \mathbb{Q}[t]$ exists such that the quadratic twists of E_1, E_2 by $d(t)$ both have positive rank over $\mathbb{Q}(t)$.

In [U] it is shown that if one allows sextic resp. quartic twists, then analogous results hold for pairs of elliptic curves with j -invariant 0 resp. 1728. Here we extend this to a special class of hyperelliptic curves.

Theorem 1.1. *Suppose $n \in \mathbb{Z}_{\geq 3}$. Given nonzero $a, b \in \mathbb{Q}$, there exists a polynomial $d(t) \in \mathbb{Q}[t]$ such that the Jacobians of the curves given by $y^2 = x^n + ad(t)$ and $y^2 = x^n + bd(t)$ both have positive rank over $\mathbb{Q}(t)$.*

In fact, more precise results will be given. For example, the question is considered whether or not it is possible to demand that the polynomial $d(t) \in \mathbb{Q}[t]$ is a square. Moreover, one can improve the result above to the case of more than two curves:

Key words and phrases. Hyperelliptic curve, twist, Mordell-Weil rank, Jacobian.

Theorem 1.2. *Suppose $n \in \mathbb{Z}_{\geq 3}$. Given nonzero $a, b, c \in \mathbb{Q}$, there exists a polynomial $d(t) \in \mathbb{Q}[t]$ such that the Jacobians of the curves given by $y^2 = x^n + ad(t)$ and $y^2 = x^n + bd(t)$ and $y^2 = x^n + cd(t)$ all have positive rank over $\mathbb{Q}(t)$.*

Theorem 1.3. *Suppose $n \in \mathbb{Z}_{\geq 3}$ is odd. Given nonzero $a_1, a_2, a_3, a_4 \in \mathbb{Q}$, there exists a polynomial $d(t) \in \mathbb{Q}[t]$ such that the Jacobians of the curves given by $y^2 = x^n + a_j d(t)$ all have positive rank over $\mathbb{Q}(t)$.*

Generalities concerning twists of varieties and more in particular twists of curves can be found in [MT]. Note that in the special case that n is even, the curves considered here are equipped with two rational points ∞_+, ∞_- ‘at infinity’. The difference $(\infty_+) - (\infty_-)$ then defines a nontrivial point in the Jacobian. However, this is a torsion point as follows by taking the divisor of the function $y + x^{n/2}$. This is a very special case of a topic already studied by Abel; see, for example, work of Schinzel [Sch], Hellegouarch and Lozach [HL], and Berry [Be] and many references they provide.

The proof of our result consists of two parts. Given a point $(x(t), y(t))$ on a curve with equation $y^2 = x^n + a \cdot d(t)$, we need a condition implying that this point minus a point at infinity defines a point of infinite order in the Jacobian. This is done by adapting ideas of [ST] to the present situation. Next, we need a rational function $d(t)$ and rational points $(x_a(t), y_a(t))$ resp. $(x_b(t), y_b(t))$ on the curve with equation $y^2 = x^n + ad(t)$ resp. $y^2 = x^n + bd(t)$. To this end, we construct rational curves on the threefold $\mathcal{X}$ with equation

$$\mathcal{X} : b(y_a^2 - x_a^n) = a(y_b^2 - x_b^n).$$

Parametrizing such a rational curve as $t \mapsto (x_a(t), y_a(t), x_b(t), y_b(t))$ gives us the required points by taking $d(t) := (y_a(t)^2 - x_a(t)^n)/a$. If one moreover demands that $d(t)$ is a square, then instead of $\mathcal{X}$ one considers the threefold $\mathcal{Y}$ given by the two equations

$$\mathcal{Y} : z^2 = b(y_a^2 - x_a^n) = a(y_b^2 - x_b^n),$$

which defines a double cover of $\mathcal{X}$.

Section 2 provides details on the method used to show that certain divisors have infinite order. Section 3 contains the construction of rational curves on the threefolds $\mathcal{X}$ and $\mathcal{Y}$, resulting in the proof of Theorem 1.1. Finally, in Section 4 we prove the Theorems 1.2 and 1.3.

2. INFINITE ORDER

In this section take $n \in \mathbb{Z}_{\geq 3}$. Suppose K is a field of characteristic not dividing $2n$. Fix $a \in K$ with $a \neq 0$ and take $d(t) \in K[t]$ of positive degree,

such that $d(t)$ is not divisible by a nonconstant $\text{lcm}(2, n)$ th power in $K[t]$. Let $\alpha \in K$ be the leading coefficient of $d(t)$. Define the hyperelliptic curve C_0/K by the equation

$$C_0 : y^2 = x^n + a\alpha$$

and $C/K(t)$ by

$$C : y^2 = x^n + ad(t).$$

Fix a point $\infty \in C(K(t))$ at infinity. For any affine point $P = (x(t), y(t)) \in C(K(t))$, we will study the divisor class $(P) - (\infty)$ in the Jacobian of C .

Write $d(t) = \alpha f(t)^m$ with $f(t) \in K[t]$ monic and m the largest divisor of $\text{lcm}(2, n)$ such that $d(t)$ is, up to a constant, an m th power. By the assumptions, $1 \leq m < \text{lcm}(2, n)$. Define $\ell := \text{lcm}(2, n)/m \in \mathbb{Z}_{\geq 2}$. For every extension field $L \supset K$, the polynomial $s^\ell - f(t)$ is irreducible in $L[t, s]$ since otherwise $f(t)$ would be a k th power for some divisor $k > 1$ of ℓ , which is not the case. Hence we have an irreducible curve D/K , defined by

$$D : s^\ell = f(t).$$

Note that the curve D is taken such that over the function field $K(D) \supset K(t) \supset K$, the curves C and C_0 are isomorphic: over $K(D)$ one has

$$d(t) = \alpha f(t)^m = \alpha s^{\text{lcm}(2, n)},$$

hence one obtains the isomorphism

$$C \xrightarrow{\sim} C_0 : (x, y) \mapsto (xs^{-\text{lcm}(2, n)/n}, ys^{-\text{lcm}(2, n)/2}).$$

Now suppose that $P = (x(t), y(t)) \in C(K(t))$ is an affine point of C over $K(t)$. Using the isomorphism above, P defines a morphism $\varphi_P : D \rightarrow C_0$ given by

$$\varphi_P : (t, s) \mapsto (x(t)s^{-\text{lcm}(2, n)/n}, y(t)s^{-\text{lcm}(2, n)/2}).$$

The Jacobian of C_0 will be denoted J_0 . Composing φ_P with an embedding $C_0 \rightarrow J_0$ we obtain a morphism, which we will also denote by φ_P , from D to J_0 . Summarizing, this defines

$$C(K(t)) \longrightarrow \text{Mor}(D, J_0) : P \mapsto \varphi_P.$$

(Note that the point(s) at infinity on C give rise to constant morphisms.) Since $\text{Mor}(D, J_0)$ is a group (in fact, one may identify it with $J_0(K(D))$), the above assignment by linearity extends to a homomorphism

$$\varphi : J(K(t)) \longrightarrow \text{Mor}(D, J_0).$$

Proposition 2.1. *Let $P \in C(K(t))$ with $P \notin C(K)$ and $y(P) \neq 0$. Then $\varphi((P) - (\infty)) \in \text{Mor}(D, J_0)$ has infinite order.*

In particular, this implies that $(P) - (\infty)$ defines an element of infinite order in $J(K(t))$.

The proof adapts the argument presented in Section 4 of [ST], and runs as follows. Using the above notations, suppose, on the contrary, that $\varphi((P) - (\infty))$ has finite order. This means that the map $D \rightarrow J_0$ it defines, has a finite image. Since D is absolutely irreducible, so is this image, which implies it consists of only one point. This point is the image of D under the composition $D \xrightarrow{\varphi_P} C_0 \rightarrow J_0$. Because $C_0 \rightarrow J_0$ is injective, one concludes that $\varphi_P : D \rightarrow C_0$ is constant. Using the given conditions on P , a direct verification shows that this is impossible. $\square$

Remark 2.2. The equation $y^2 = x^n + \alpha a f(t)^m$ with $f \in K[t]$ of positive degree obviously has no solutions $(x, y) \in K \times K$. Hence the only points in $C(K)$ are the points at infinity. Furthermore, the definition of the integer m in this section implies, that a point in $C(K(t))$ with y -coordinate 0 exists only when $m = n$ and $-\alpha a$ is an n th power in K . It is easy to verify that for such a point P , indeed $(P) - (\infty)$ defines a torsion point in $J(K(t))$ (of order 2 when n is odd; of order dividing n otherwise).

3. RATIONAL CURVES ON SOME THREEFOLDS

In this section, a, b are nonzero rational numbers. First, the threefold $\mathcal{X}$ with equation $b(y_1^2 - x_1^n) = a(y_2^2 - x_2^n)$ is studied.

Lemma 3.1. $\mathcal{X}$ is birational to $\mathbb{A}^3$ over $\mathbb{Q}$.

Proof. First suppose that $n = 2m + 1$ is odd. The birational map

$$(x_1, y_1, x_2, y_2) \mapsto (T, p, q, r) := (x_1, y_1 \cdot x_1^{-m}, x_2/x_1, y_2 \cdot x_1^{-m})$$

shows that $\mathcal{X}$ is birational to the threefold given by

$$(aq^n - b)T = ar^2 - bp^2.$$

Since this equation has degree one in the variable T , the lemma follows for n odd.

Now suppose $n = 2m$ is even. In this case, the map

$$(x_1, y_1, x_2, y_2) \mapsto (T, u, v, w) := (y_1 - x_1^m, x_1, x_2, (y_2 - x_2^m)/(y_1 - x_1^m))$$

shows that $\mathcal{X}$ is birational to the threefold given by

$$(aw^2 - b)T = -2(awv^m - bu^m).$$

Again, the equation has degree one in the variable T , which finishes the proof of the lemma. $\square$

It is now straightforward to finish the proof of our main result. Namely, take, depending on n being even or odd, three (sufficiently general) rational functions $p(t), q(t), r(t)$ (or $u(t), v(t), w(t)$). Use the linear equation in the proof of the lemma above, to find a corresponding $T(t)$. From this, via the birational map given above, find $x_1(t), y_1(t), x_2(t), y_2(t)$ and proceed as explained in the introduction of this paper to obtain a rational function $d(t)$. Clearing denominators one ends up in a situation where Proposition 2.1 is applicable, and the result follows. $\square$

Now consider the threefold $\mathcal{Y}$, which corresponds to the case that moreover one desires the polynomial $d(t)$ in the main theorem to be a square. For this, one uses the birational map from $\mathcal{X}$ to $\mathbb{A}^3$ from the lemma. Since $\mathcal{Y}$ is a double cover of $\mathcal{X}$, this yields an explicit birational map over $\mathbb{Q}$ from $\mathcal{Y}$ to a double cover of $\mathbb{A}^3$. As before, the cases of odd n and even n are considered separately.

First, suppose $n = 2m + 1$ is odd. Using the variables p, q, r introduced before, one finds that $\mathcal{Y}$ is birational to the threefold with equation

$$(aq^n - b)h^2 = (p^2q^n - r^2).$$

Now put $q = u^2$, where u is an indeterminate. Over $\mathbb{Q}(u)$ the above homogeneous quadratic equation in the variables p, r, h defines a quadratic curve equipped with a rational point $(p : r : h) = (1 : u^n : 0)$. It is straightforward to parametrize this quadratic curve over $\mathbb{Q}(u)$. As a result, one obtains a dominant, rational map of degree 2 defined over $\mathbb{Q}$ from $\mathbb{A}^3$ to the threefold $\mathcal{Y}$. We have shown the following.

Corollary 3.2. *In case n is odd, for any pair a, b of nonzero rational numbers, one can choose the polynomial $d(t) \in \mathbb{Q}[t]$ described in Theorem 1.1 to be a square.*

Next, take $n = 2m$ even. Using the variables u, v, w, T and $\zeta := z/(2 \cdot (aw^2 - b))$ one obtains the equation

$$\zeta^2 = -abw(u^mw - v^m)(av^mw - bu^m)$$

for a threefold birational over $\mathbb{Q}$ to $\mathcal{Y}$. Observe that this equation defines an elliptic curve E over the field $\mathbb{Q}(u, v)$. One way of constructing rational curves over $\mathbb{Q}$ on $\mathcal{Y}$ would be to find nontrivial points in $E(\mathbb{Q}(u, v))$. Indeed, if $(w(u, v), \zeta(u, v))$ is such a point, then for general rational functions $u(t), v(t)$ one obtains $w(t) := w(u(t), v(t))$ and this easily leads to a rational curve as desired. Unfortunately, this idea fails, as the following proposition shows.

Proposition 3.3. *With notations as above, $E(\mathbb{Q}(u, v))$ is a finite group.*

Proof. Put $Y := a^2bu^mv^m\zeta$ and $X := -a^2bu^mv^mw$, then the equation for E becomes

$$Y^2 = X(X + a^2bv^{2m})(X + ab^2u^{2m}).$$

Let K be an algebraic closure of $\mathbb{Q}(v)$. We will show the even stronger result that over $K(u)$, the Mordell-Weil group is finite.

Observe that our elliptic curve over $K(u)$ is the generic fiber of an elliptic surface $\mathcal{E} \rightarrow \mathbb{P}^1$ over K . This elliptic surface has fibers of type I_{4m} over 0 and over ∞ , and fibers of type I_2 over all u such that $bu^{2m} = av^{2m}$. From standard theory of elliptic surfaces (compare [SchS]; especially Sections 5, 6, 10) one obtains that the second Betti number $h^2(\mathcal{E}) = 12m - 2$ and the Hodge number $h^{0,2}(\mathcal{E}) = m - 1$. As a result, the rank $\rho(\mathcal{E})$ of the Néron-Severi group of $\mathcal{E}$ satisfies $\rho \leq h^2 - 2h^{0,2} = 10m$. The Shioda-Tate formula now implies that the Mordell-Weil rank r of $\mathcal{E} \rightarrow \mathbb{P}^1$ over K satisfies

$$r + 2 + (4m - 1) + (4m - 1) + 2m \cdot (2 - 1) \leq 10m,$$

hence $r = 0$. This implies the proposition. $\square$

The argument above shows that for every $m > 0$, the elliptic surface $\mathcal{E} \rightarrow \mathbb{P}^1$ over K is a so-called semi-stable extremal elliptic surface (with geometric genus $p_g = m - 1$); compare [Kl]. For $m \in \{1, 2, 4\}$ the surface corresponds to certain torsion-free genus zero congruence subgroups of $\mathrm{PSL}(2, \mathbb{Z})$ (of index 12, 24 and 48, respectively); see [TY].

The (finite) group of sections of $\mathcal{E} \rightarrow \mathbb{P}^1$ over K is in fact a group isomorphic to $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$. Indeed, a straightforward calculation (compare [Si, Chapter X, Prop. 1.4]) shows that in $E(K(u))$ the point $(0, 0)$ is divisible by 2 but not by 4, and the other points of order 2 are not divisible by 2. So the 2-part of $E(K(u))$ is isomorphic to $\mathbb{Z}/2 \times \mathbb{Z}/4\mathbb{Z}$. If it would contain a point of order $p > 2$ prime, then the modular curve corresponding to $\Gamma(4; 2, 1, 1) \cap \Gamma_1(p)$ (see [TY] for notations) would be a rational curve, which is not the case.

Note that the points of order 4 in $E(K(u))$ are obtained by taking $X = \alpha u^m$ in which $\alpha \in K$ satisfies $\alpha^2 = a^3b^3v^{2m}$. In particular, $\alpha \notin \mathbb{Q}(v)$ in general. The leading coefficient $\beta \in K$ of the corresponding Y -coordinate $Y = \beta u^{2m} + \dots$ satisfies $\beta^2 = a^4b^5v^{2m}$. Hence only when a, b are both squares in $\mathbb{Q}$, the point(s) of order 4 can actually be used to construct rational curves as desired on the threefold $\mathcal{Y}$.

4. THREE- AND FOUR TUPLES OF CURVES

In this last section Theorems 1.2 and 1.3 are proven. Obviously, Theorem 1.3 implies the case of Theorem 1.2 with n odd. So we first prove Theorem 1.2 assuming that $n = 2m$ is even.

Let m be a positive integer, and $a, b, c \in \mathbb{Q}^\times$. Consider the four dimensional variety $\mathcal{Z} = \mathcal{Z}_m$ defined by

$$\mathcal{Z} : bc(y_1^2 - x_1^{2m}) = ac(y_2^2 - x_2^{2m}) = ab(y_3^2 - x_3^{2m}).$$

Using the same ideas as in Section 3, we will construct sufficiently general (meaning that $y_1^2 - x_1^{2m}$ is nonconstant on them, and moreover not equal to a times a $2m$ th power) rational curves in $\mathcal{Z}$ over $\mathbb{Q}$. Put $K := \mathbb{Q}(x_1, x_2, x_3)$. The equations defining $\mathcal{Z}$ may be regarded as the equations defining a genus one curve E over K . This curve E contains the K -rational points

$$(y_1, y_2, y_3) = (\pm x_1^m, \pm x_2^m, \pm x_3^m).$$

It is straightforward (e.g., using the computer algebra system Magma) to use one of these points as zero element for a group law on E and calculate a nontrivial linear combination of the other points. As an example of this one obtains

$$\begin{aligned} y_1 &= \frac{(3a^2x_3^{4m}x_2^{4m} - 2acx_1^{2m}x_2^{4m}x_3^{2m} - 2abx_3^{4m}x_1^{2m}x_2^{2m} - c^2x_1^{4m}x_2^{4m} + 2bcx_1^{4m}x_2^{2m}x_3^{2m} - b^2x_3^{4m}x_1^{4m})x_1^m}{a^2x_3^{4m}x_2^{4m} - 2abx_3^{4m}x_1^{2m}x_2^{2m} + b^2x_3^{4m}x_1^{4m} - 2acx_1^{2m}x_2^{4m}x_3^{2m} - 2bcx_1^{4m}x_2^{2m}x_3^{2m} + c^2x_1^{4m}x_2^{4m}}, \\ y_2 &= \frac{(a^2x_3^{4m}x_2^{4m} - 2acx_1^{2m}x_2^{4m}x_3^{2m} + 2abx_3^{4m}x_1^{2m}x_2^{2m} + c^2x_1^{4m}x_2^{4m} + 2bcx_1^{4m}x_2^{2m}x_3^{2m} - 3b^2x_3^{4m}x_1^{4m})x_2^m}{a^2x_3^{4m}x_2^{4m} - 2abx_3^{4m}x_1^{2m}x_2^{2m} + b^2x_3^{4m}x_1^{4m} - 2acx_1^{2m}x_2^{4m}x_3^{2m} - 2bcx_1^{4m}x_2^{2m}x_3^{2m} + c^2x_1^{4m}x_2^{4m}}, \\ y_3 &= -\frac{(a^2x_3^{4m}x_2^{4m} - 2abx_3^{4m}x_1^{2m}x_2^{2m} + b^2x_3^{4m}x_1^{4m} + 2acx_1^{2m}x_2^{4m}x_3^{2m} + 2bcx_1^{4m}x_2^{2m}x_3^{2m} - 3c^2x_1^{4m}x_2^{4m})x_3^m}{a^2x_3^{4m}x_2^{4m} - 2abx_3^{4m}x_1^{2m}x_2^{2m} + b^2x_3^{4m}x_1^{4m} - 2acx_1^{2m}x_2^{4m}x_3^{2m} - 2bcx_1^{4m}x_2^{2m}x_3^{2m} + c^2x_1^{4m}x_2^{4m}}. \end{aligned}$$

In fact, the following Magma code produces this (we use the notation $K = \mathbb{Q}(a, b, c, x_1, x_2, x_3)$ and take $m = 1$):

```
> P<y1,y2,y3,y4>:=ProjectiveSpace(K,3);
> C:=Curve(P,[a*c*(y2^2-y4^2*x2^2)-b*c*(y1^2-y4^2*x1^2),
               a*c*(y2^2-y4^2*x2^2)-b*a*(y3^2-y4^2*x3^2)]);
> P:=C![x1,x2,x3,1];
> E,phi:=EllipticCurve(C,P);
> Q:=C![-x1,x2,x3,1];
> S:=C![x1,x2,-x3,1];
> som:=phi(Q)+phi(S);
> Inverse(phi)(som);
```

It is easy to find rational curves in $\mathcal{Z}$ as desired from this. Hence Theorem 1.2 follows for even n . $\square$

Lastly, consider $a, b, c, d \in \mathbb{Q}^\times$ and an integer $m \geq 1$. Clearly it suffices to prove Theorem 1.3 in the case that a, b, c, d are pairwise distinct. We assume

this condition from now on (it will guarantee that the variety introduced below is geometrically irreducible).

Define the five dimensional variety $\mathcal{W}$ by

$$\frac{y_1^2 - x_1^{2m+1}}{a} = \frac{y_2^2 - x_2^{2m+1}}{b} = \frac{y_3^2 - x_3^{2m+1}}{c} = \frac{y_4^2 - x_4^{2m+1}}{d}.$$

Let u be an indeterminate. Working over $\mathbb{Q}(u)$, we intersect $\mathcal{W}$ with the linear space defined by

$$u^{-2}x_1 = x_2 = x_3 = x_4.$$

The intersection is a surface $\mathcal{S}$, in the variables y_1, y_2, y_3, y_4 and x ($= x_2 = x_3 = x_4 = x_1/u^2$) given by

$$bcd(y_1^2 - u^{4m+2}x^{2m+1}) = acd(y_2^2 - x^{2m+1}) = abd(y_3^2 - x^{2m+1}) = abc(y_4^2 - x^{2m+1}).$$

Using new variables $\eta_j = y_j x^{-m}$ one shows that $\mathcal{S}$ is birational over $\mathbb{Q}(u)$ to the surface $\mathcal{T}$ with equations

$$bcd(\eta_1^2 - u^{4m+2}x) = acd(\eta_2^2 - x) = abd(\eta_3^2 - x) = abc(\eta_4^2 - x).$$

Eliminating x from these equations shows that $\mathcal{T}$ is birational over $\mathbb{Q}(u)$ to the cone in $\mathbb{A}^3$ over the curve C defined as

$$C : \begin{cases} (d-c)(d\eta_2^2 - b) = (d-b)(d\eta_3^2 - c) \\ (d-c)(d\eta_1^2 - a) = (du^{4m+2} - a)(d\eta_3^2 - c). \end{cases}$$

The curve C has genus one and contains the rational points

$$(\eta_1, \eta_2, \eta_3) = (\pm u^{2m+1}, \pm 1, \pm 1).$$

Using one of these points as zero for a group law on C , it is easy to combine others and construct new $\mathbb{Q}(u)$ -rational points on C . An example of a point obtained in this way, using the Magma system quite analogously as in the case described above, is

$$\eta_1 = \frac{v(-c^2v^4 + 2bcv^4 + 2cdv^4 - b^2v^4 + 2bdv^4 - d^2v^4 - 2acv^2 - 2abv^2 - 2adv^2 + 3a^2)}{c^2v^4 - 2bcv^4 + 2cdv^4 + b^2v^4 + 2bdv^4 - 3d^2v^4 - 2acv^2 - 2abv^2 + 2adv^2 + a^2},$$

$$\eta_2 = \frac{c^2v^4 + 2bcv^4 - 2cdv^4 - 3b^2v^4 + 2bdv^4 + d^2v^4 - 2acv^2 + 2abv^2 - 2adv^2 + a^2}{c^2v^4 - 2bcv^4 + 2cdv^4 + b^2v^4 + 2bdv^4 - 3d^2v^4 - 2acv^2 - 2abv^2 + 2adv^2 + a^2},$$

$$\eta_3 = -\frac{-3c^2v^4 + 2bcv^4 + 2cdv^4 + b^2v^4 - 2bdv^4 + d^2v^4 + 2acv^2 - 2abv^2 - 2adv^2 + a^2}{c^2v^4 - 2bcv^4 + 2cdv^4 + b^2v^4 + 2bdv^4 - 3d^2v^4 - 2acv^2 - 2abv^2 + 2adv^2 + a^2}.$$

in which $v = u^{2m+1}$. Now it is straightforward, as in the previous cases, to complete the proof of Theorem 1.3 (and hence of Theorem 1.2). $\square$
